# Multiplexing

$$I = N\Phi_{incident} \frac{\partial^2 \sigma}{\partial \Omega \partial E_{final}} \Delta \Omega \Delta E_{final}$$

$$\text{Resolution} \propto \Delta \Omega \Delta E_{final}$$

Solution : measure several  $I_{ij}(\Delta \Omega_i, \Delta E_j^{final})$

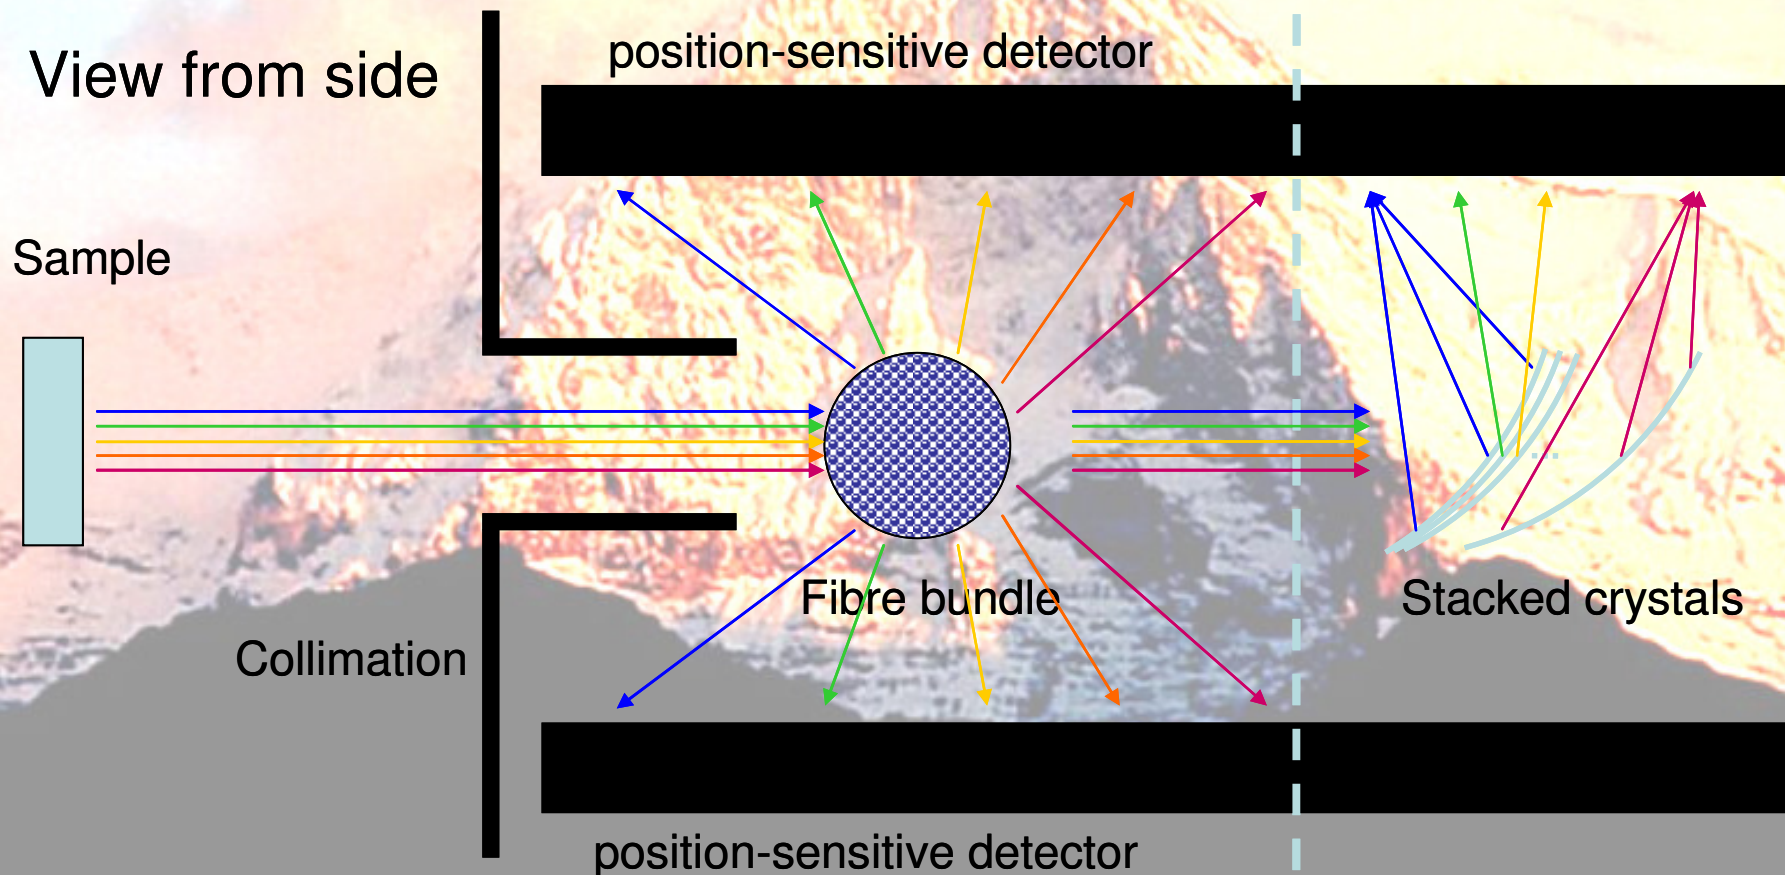

# Multiple Energy Analysis

- Time-of-flight:
  - Requires pulsed monochromatic incident beam
  - Continuous source: must chop the beam
  - Pulsed source: must monochromatize the beam
- Bragg-diffraction:
  - E.g. triple-axis spectrometers
  - scatters one energy – the rest continue
  - Idea: have consecutive crystals, scatter different energies

# Two approaches

- Crystal-fibre bundles
- Consecutive stack of crystals blades

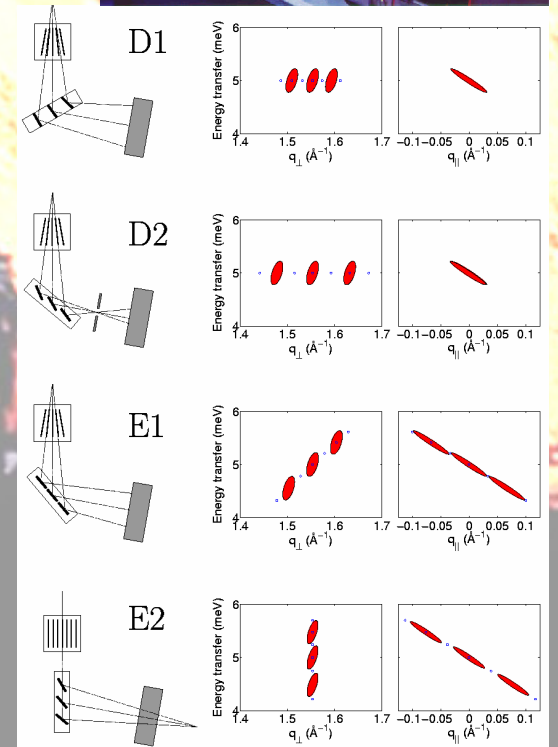

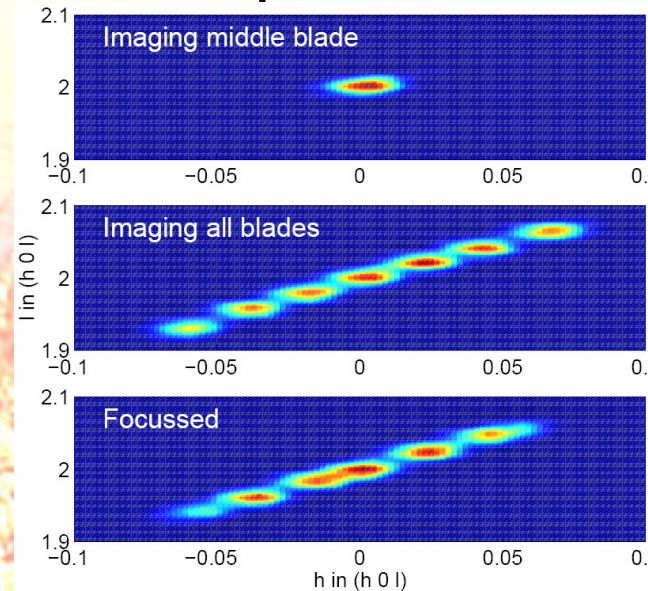

# The RITA-concept

- Divide TAS analyser in multiple blades
  - SPINS
  - UFO
  - IN8-IMPS
  - PUMA-project

- Limitation:

#neutrons = total analyser area

Difficult to get more than 3-4 x TAS

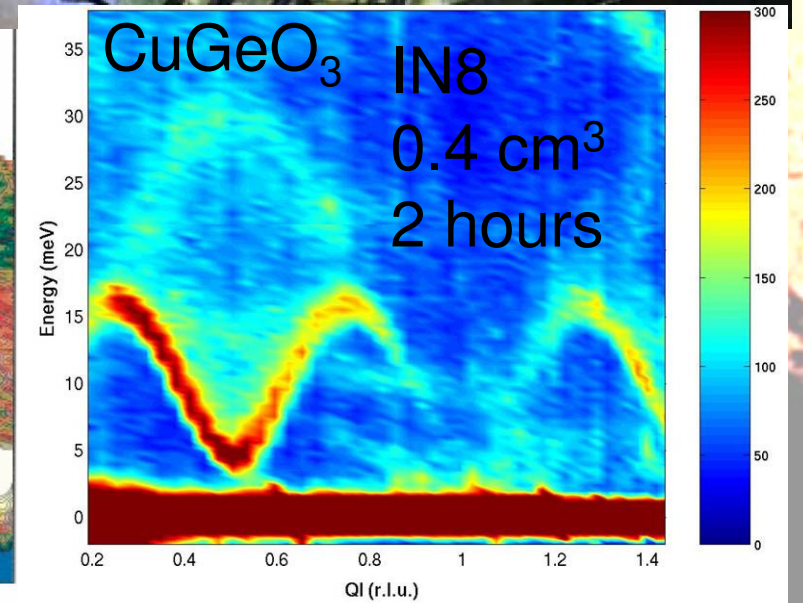

# Multiple angles

- Neutrons scatter in 'all' directions
- Collect more angles
  - MAD-box
  - Flat-cone
  - MACS
  - ...
- Beats TOF for:
  - small samples
  - Field/pressure

## TAS

- Focus on one Point
- Flexible
- Already “optimal” (IN8, IN20..)

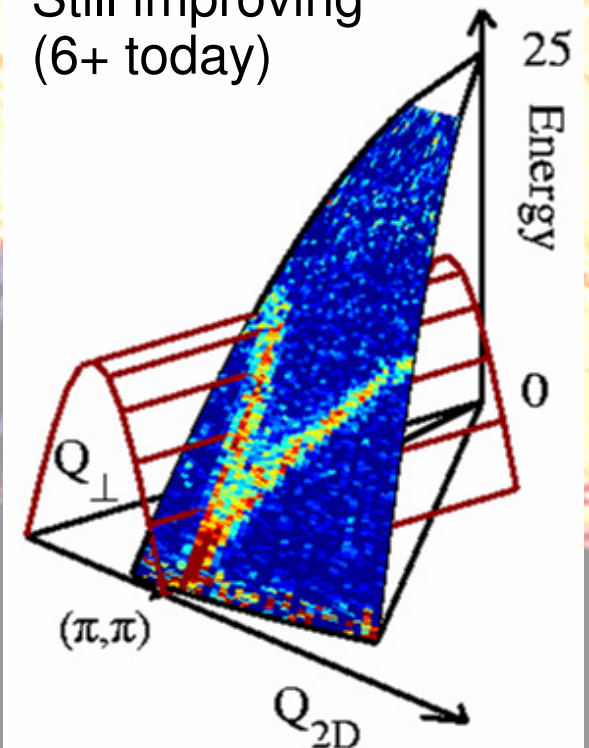

## Multi-TAS

- a line in momentum-energy-space
- More Neutrons recorded than TAS
- More flexible than TOF
- Parametric studies

## TOF

- 2-3D manifold
- Overview – sees “everything”
- Less flexible
- Still improving (6+ today)

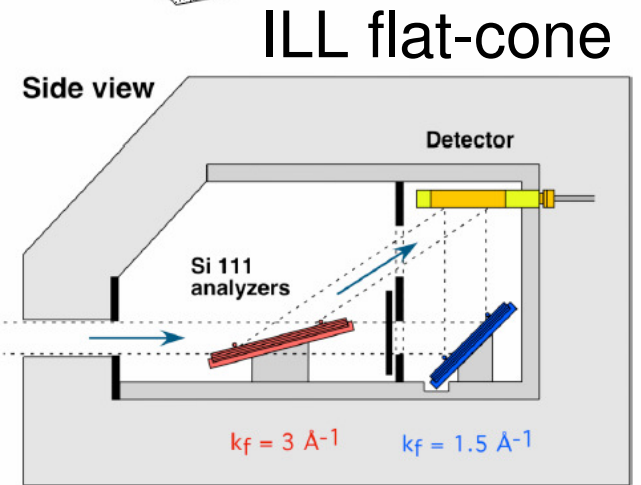

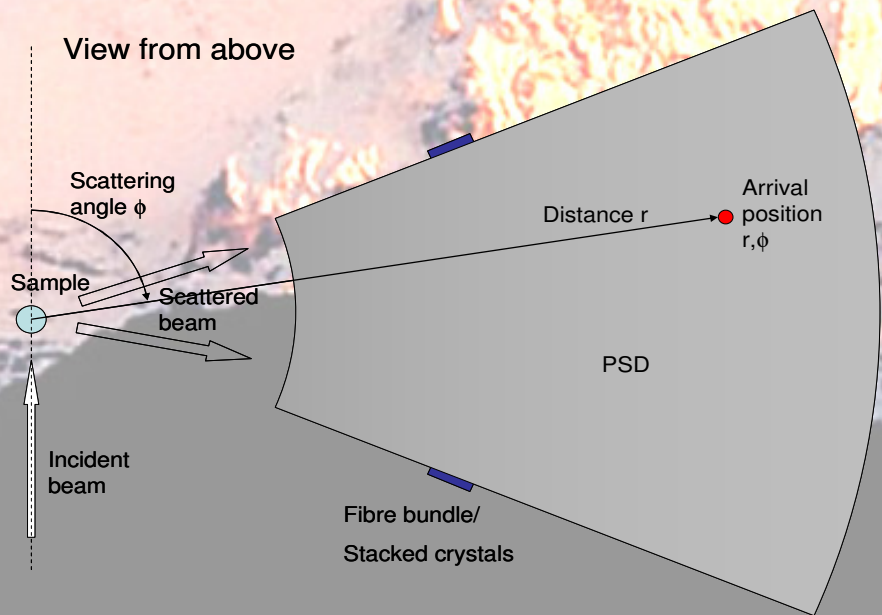

# Continuous angles

- Geometry of many analysers and detectors?

- Dead angles
- Solution:  
scatter vertically

# Continuous Angle + Multiple Energy Analysis

# Work-plan

- Invite more interesting
- Material choices:
  - Crystal fibres
  - Stacked crystals: PG or Si/Ge?
- Geometries:
  - Compromises: coverage, resolution, bck, size & price:  
Monte Carlo
- Prototyping:
  - Reflectivities, absorption, background
- Adaptation of design to specific instrument characteristics
- Data-analysis / experiment planning tools
